Assertion #1

Climate change adaptation is one of the most complex and daunting challenges ever faced by human civilization.

Temperature Anomaly Record: 1880-2016

Global Land and Ocean Temperature Anomalies, January-December

What does it mean for Florida?

Climate change models are unclear about the following impacts for Florida:

- 1) Drought
- 2) Flooding
- 3) Extreme heat
- 4) Freezes
- 5) Hurricane frequency (although storms are likely to be stronger)

Sea-Level Rise is THE big problem for Florida

NOAA: 'Nuisance flooding' an increasing problem as coastal sea levels rise

Study looks at more than 60 years of coastal water level and local elevation data changes

July 28, 2014

Eight of the top 10 U.S. cities that have seen an increase in so-called "nuisance flooding"—which causes such public inconveniences as frequent road closures, overwhelmed storm drains and compromised infrastructure—are on the East Coast, according to a new NOAA technical report.

This nuisance flooding, caused by rising sea levels, has increased on all three U.S. coasts, between 300 and 925 percent since the 1960s.

The report, [Sea Level Rise and Nuisance Flood Frequency Changes around the United States](#), also finds Annapolis and Baltimore, Maryland, lead the list with an increase in number of flood days of more than 920 percent since 1960. Port Isabel, Texas, along the Gulf coast, showed an increase of 547 percent, and nuisance flood days in San Francisco, California increased 364 percent.

"Achieving resilience requires understanding environmental threats and vulnerabilities to combat issues like sea level rise," says Holly Bamford, Ph.D., NOAA assistant administrator of the National Ocean Service. "The nuisance flood study provides the kind of actionable environmental intelligence that can guide coastal resilience efforts."

"As relative sea level increases, it no longer takes a strong storm or a hurricane to cause flooding," said William Sweet, Ph.D., oceanographer at NOAA's [Center for Operational Oceanographic Products and Services \(CO-OPS\)](#) and the report's lead author. "Flooding now occurs with high tides in many locations due to climate-related sea level rise, land subsidence and the loss of natural barriers. The effects of rising sea levels along most of the continental U.S. coastline are only going to become more noticeable and much more severe in the coming decades, probably more so than any other climate-change related factor."

The study was conducted by scientists at CO-OPS, who looked at data from 45 [NOAA water level gauges](#) with long data records around the country and compared that to reports of number of days of nuisance floods.

Millions projected to be at risk from sea-level rise in the continental United States

Mathew E. Hauer^{1*}, Jason M. Evans² and Deepak R. Mishra³

Sea-level rise (SLR) is one of the most apparent climate change stressors facing human society¹. Although it is known that many people at present inhabit areas vulnerable to SLR^{2,3}, few studies have accounted for ongoing population growth when assessing the potential magnitude of future impacts⁴. Here we address this issue by coupling a small-area population projection with a SLR vulnerability assessment across all United States coastal counties. We find that a 2100 SLR of 0.9 m places a land area projected to house 4.2 million people at risk of inundation, whereas 1.8 m affects 13.1 million people—approximately three times larger than indicated by current populations. These results suggest that the absence of protective measures could lead to US population movements of a magnitude similar to the twentieth century Great Migration of southern African-Americans⁵. Furthermore, our population projection approach can be readily adapted to assess other hazards or to model future per capita economic impacts.

data (that is, elevation and associated flood risk) with small-area population projections developed with a modified version of the Hammer method^{17,18} in a dynamic flood hazard model. By spatially and temporally aligning small-area population projections from coastal states in the continental United States (US) to 2100, we are able to assess who could be at risk from future SLR.

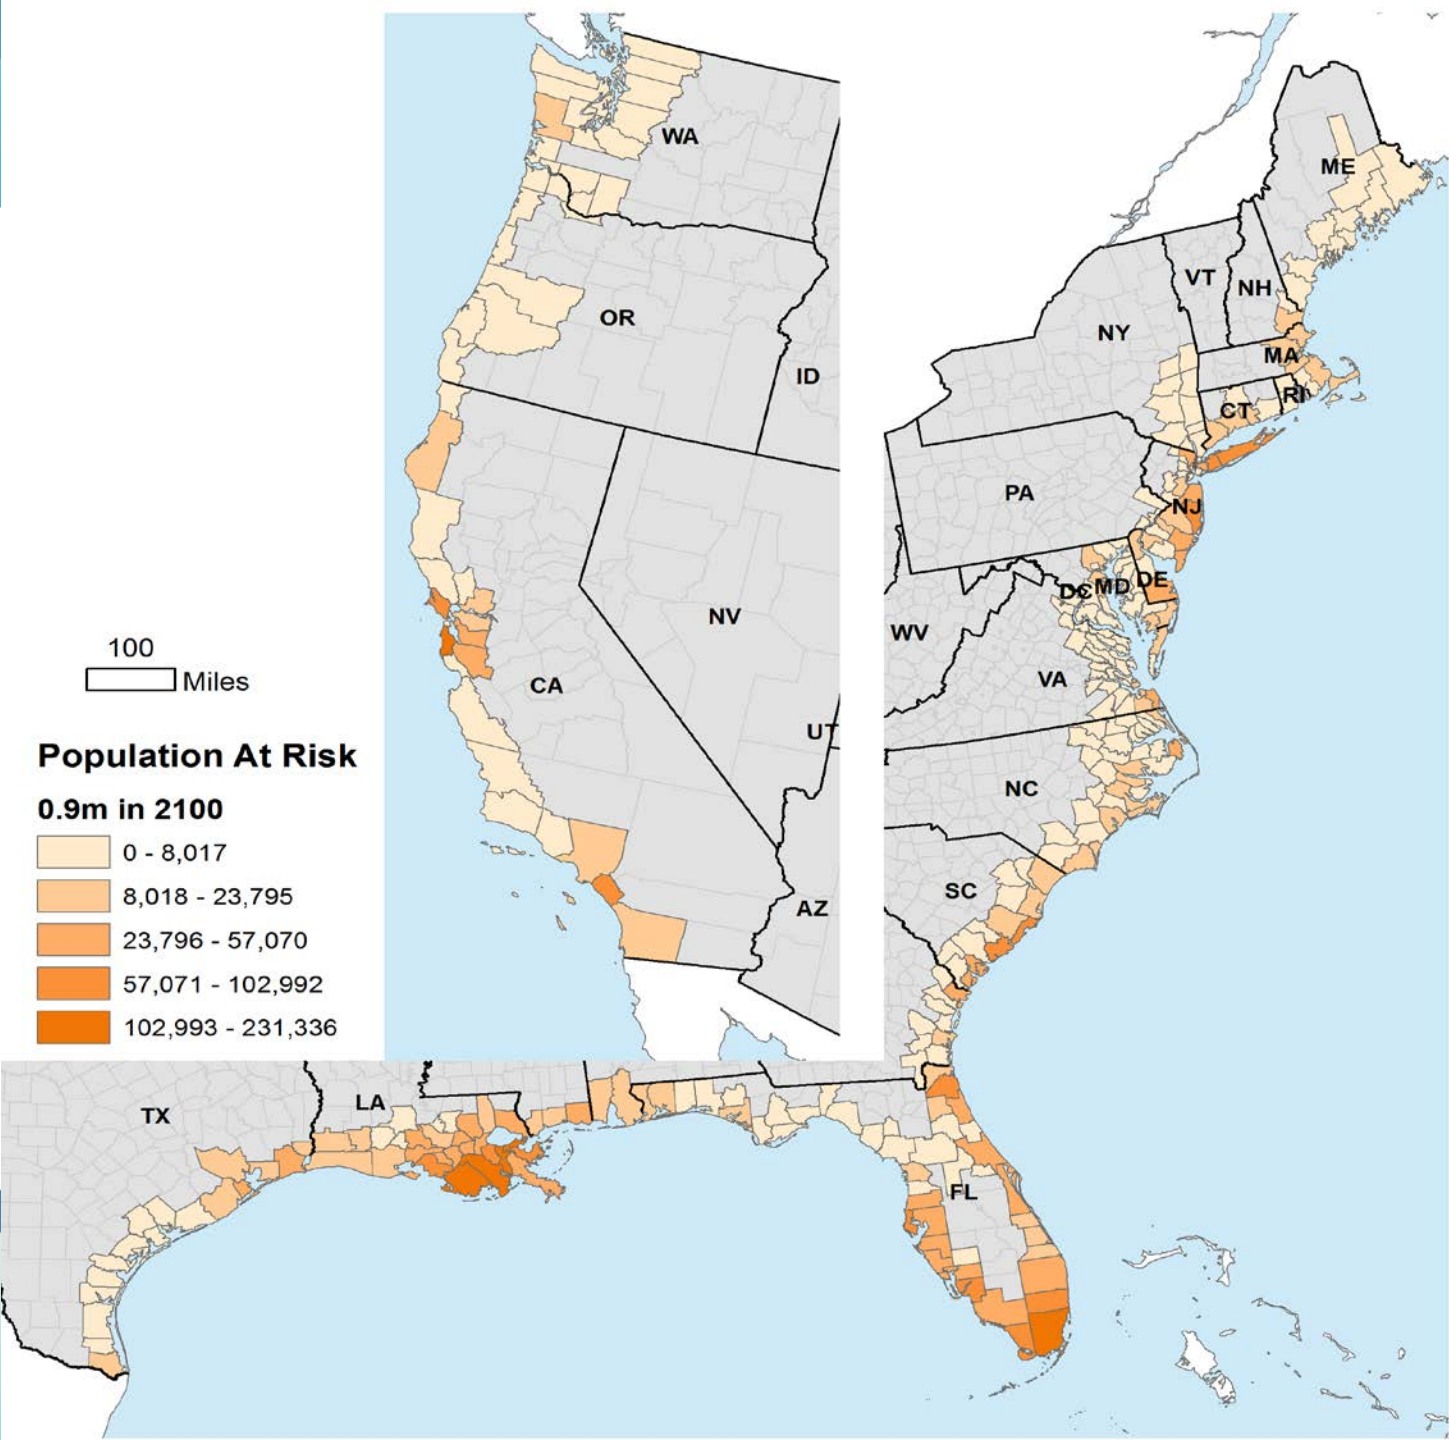

This approach addresses two fundamental questions concerning the vulnerability of future coastal populations in the United States: How many people are potentially at risk of impact from SLR? and What areas in the US are likely to experience the greatest population exposure to SLR? Accordingly, our results can be used to inform local adaptation infrastructure and growth management strategies, alerting officials to the areas where interventions and policies are most needed.

We assess the populations at risk of SLR by using the National Oceanic and Atmospheric Administration's (NOAA) 0 m through 1.8 m (6 feet) SLR data sets for twenty-two coastal states and the

and D. Mishra

Assertion #2

Very few development decisions being made today in vulnerable coastal communities are considering the consequences in a worst-case scenario at 2100.

This is understandable – even appropriate – given uncertainty about the future over such a long time-horizon.

"Scientists have very high confidence that global mean sea level will rise at least 8 inches and no more than 6.6 feet by 2100."

NOAA REPORT, DEC. 2012

BIG difference between low and high scenario

Road flooding, 3 inches of sea level rise (2030 Low)

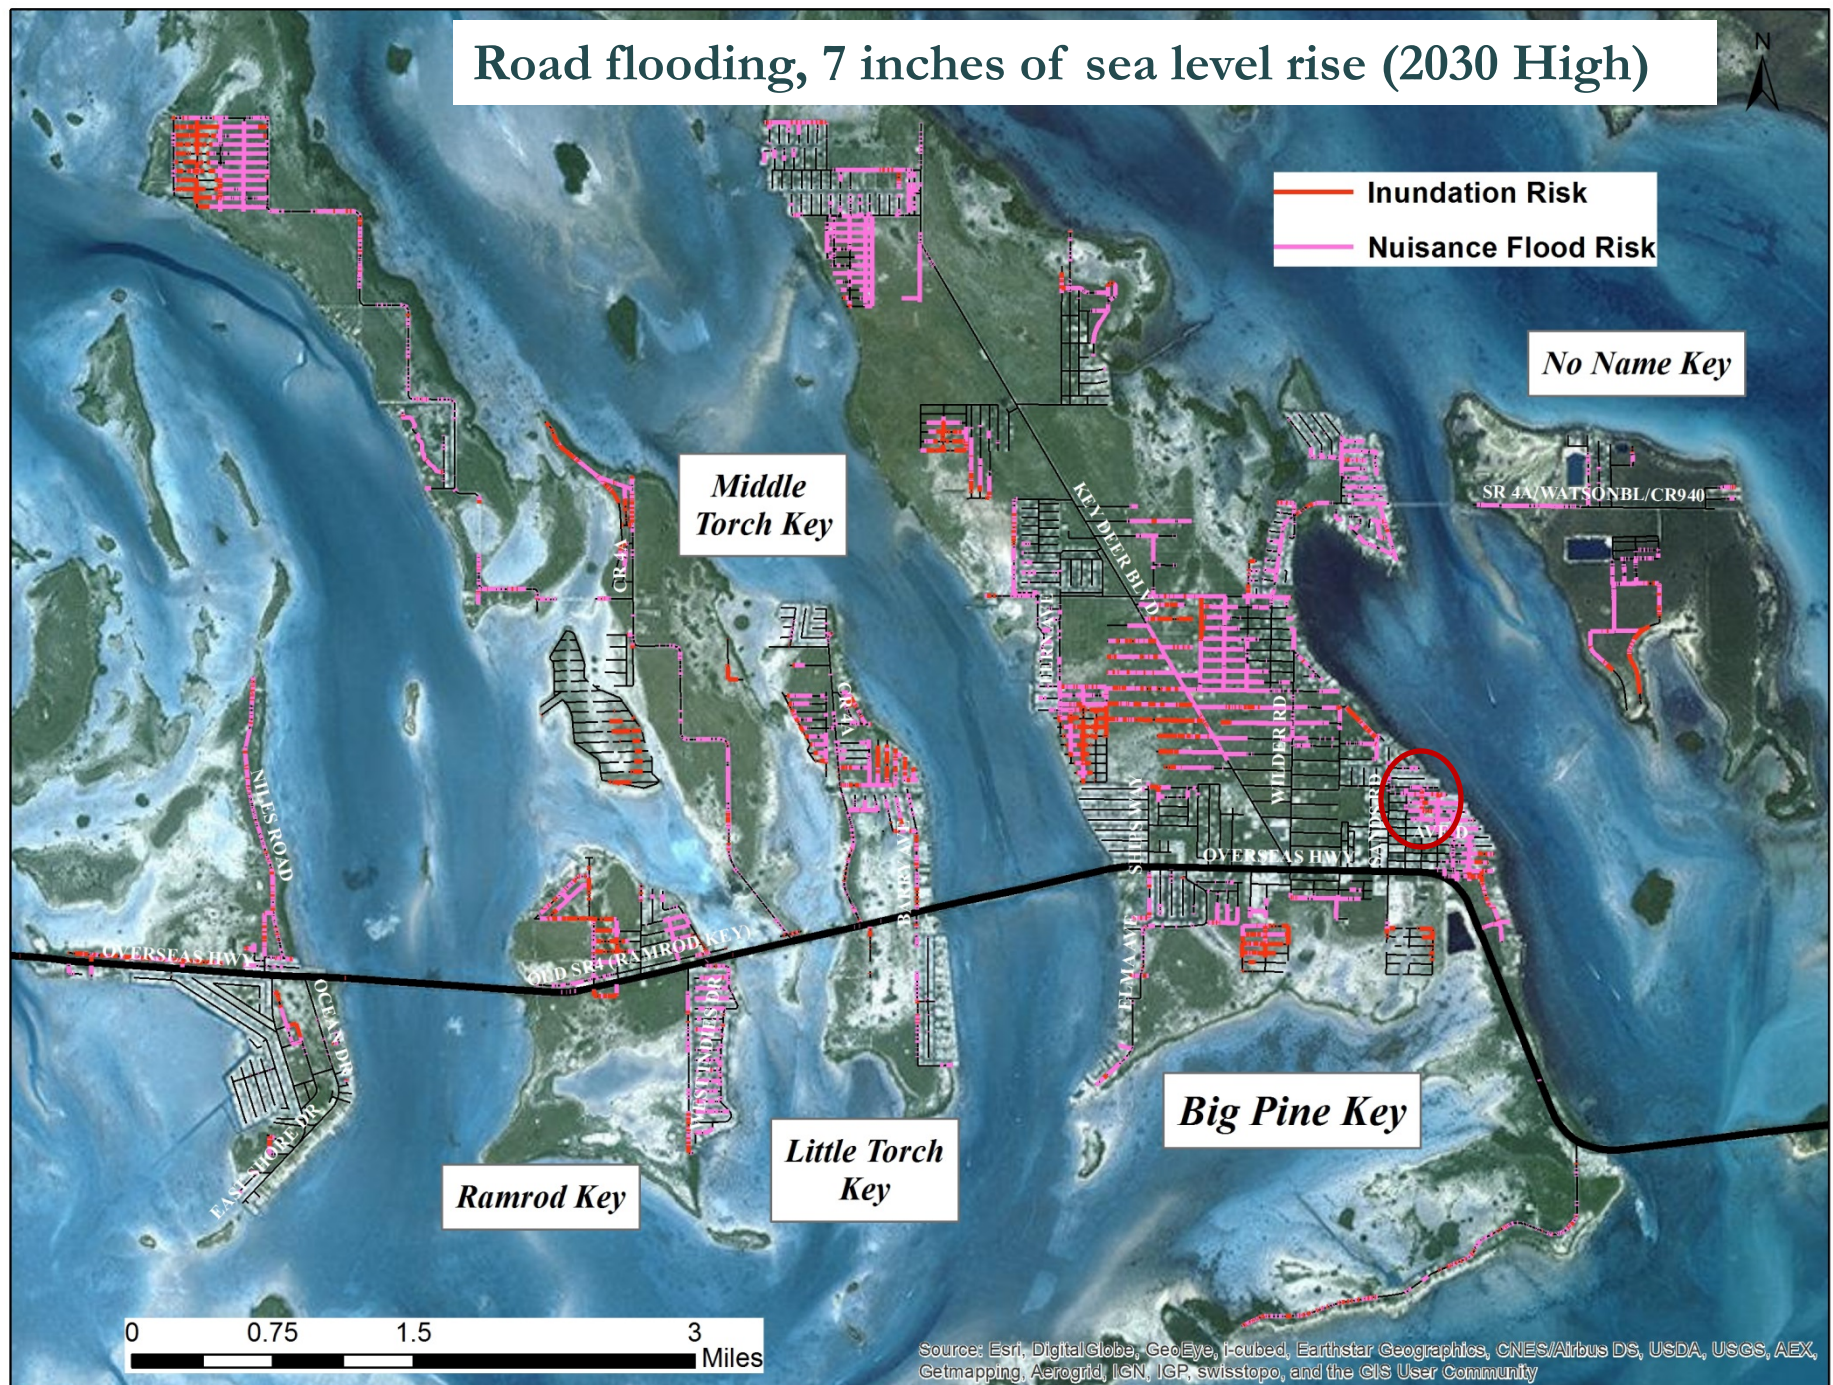

“Nuisance” flooding in Big Pine Key

September 29, 2015

**Photo credit: Greg
Corning, provided by
Monroe County staff**

Road flooding, 7 inches of sea level rise (2030 High)

Modeling: More Accurate by the Day

Policy Framing: Much More Difficult

What is an appropriate level of service for maintaining stormwater and roads under sea level rise?

Cost of upgrades and maintenance for elevation of road bed, improved drainage, pumps, etc.?

How much are citizens willing to pay for enhanced stormwater and road service?

What thresholds may make a public road no longer viable from an economic and/or engineering perspective?
